

Corneal disease has been a leading cause of blindness worldwide, after cataracts. It is a major cause of total blindness. Most applications for processing or recognizing corneal images. They have employed segmentation and quantification and quantify the disease. SUSTech-SYSU dataset. create images, convert No-linearity is introduced. number of values to zero

[illegible]

Deep learning is a powerful tool for Data Scientists who work with collecting, analyzing, predicting, and interpreting big amounts of data. In corneal ulcer research, [REDACTED]

[REDACTED]

[REDACTED] okay with a simple image. But, for bigger images or RGB big-pixel images, ANN is not easy to use. The main idea behind a pooling layer is to "accumulate" features from maps generated by convolving a filter over an image. Max Pooling is a convolution process where the Kernel extracts the maximum value of the area it convolves. If the value is more than zero it will keep it as it is. Images are [REDACTED]
